

Working with Forms

# Forms make data entry easier

Forms are used when direct entry into a table is inconvenient, to pick up errors in data entry promptly, or when too many tables make direct management of data impossible.

# **Creating forms**

The simplest way to create a form is to use the Form Wizard. Use of the Wizard to create a form is described in Chapter 8, Getting Started with Base, in the *Getting Started with LibreOffice* guide. That chapter also explains how you can further modify the form after using the Wizard.

This handbook describes the creation of a form without using the Wizard. It also describes the properties of the various types of controls in a form.

# A simple form

We start by using the task *Create Form in Design View* in the Forms area of the main Base window.

This calls up the Form Editor and the Form Shown in Design View window appears (Figure 21).

The Form Controls toolbar is docked on the left side. The Form Design toolbar (Figure 22) is docked at the bottom. If these toolbars do not appear automatically, use **View > Toolbars** to display them. Without these toolbars, it is not possible to create a form.

The blank area shows a grid of dots. This grid helps you to position the controls accurately, especially in relation to each other. The symbols at the right end of the Form Design toolbar show that the grid is visible and active.

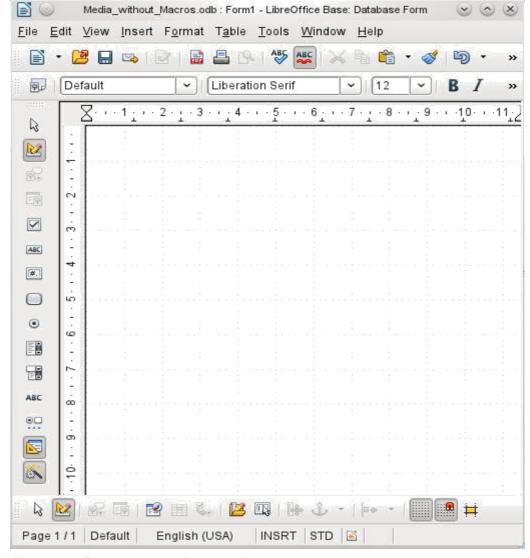

Figure 21: Form shown in Design View

# **Toolbars for form design**

Now we will create a form on the empty page. This can be done in two ways:

- Invoke the Form Navigator to set up a form, or
- Design the form controls and set up the form by using the context menu.

## Setting up a form with the Form Navigator

To display the Form Navigator, click the Form Navigator button (shown in Figure 22). A window appears (Figure 23); it shows only one folder, labeled **Forms**. This is the highest level of the area that we are editing. Several forms can be accommodated here.

Figure 22: Available buttons on the Form Design toolbar

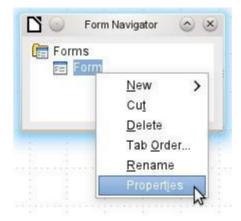

Figure 23: Using the Form Navigator to create a new form

In the Form Navigator (Figure 23), right-click on **Forms** to open a context menu. Choose **New > Form** to create a new form. The other choices in the context menu (**Open in Design Mode** and **Automatic Control Focus**) correspond to buttons in Figure 22; we will discuss them later.

The form carries the default name **Form**. You can change this name immediately or later. It has no significance unless you need to access some part of the form using macros. The only thing you need to ensure is that two elements with the same name do not occur on the same level in the folder tree.

The context menu of the form (shown below) provides the way to create form properties.

## Creating a form using a form field

The Form Controls toolbar (Figure 24) makes available some fields for your form. The first four elements are identical to those of the Form Design toolbar; they are followed by commonly used form control types (a control consists of a field plus a label).

Figure 24: Available buttons on the Form Controls toolbar

Figure 25: Available buttons on the More Controls toolbar

When you select a form control, you automatically create a form. For example, suppose you choose a text field: the cursor changes shape and a rectangular shape may be drawn on the white surface of the form. Then, on the stippled surface of the form, a text field appears.

Now you can create the form by right -clicking and using the **context menu** for the control (Figure 26).

Select the **Form** menu option (highlighted in the illustration) to set properties for the form you have just created. The form has the default name Form.

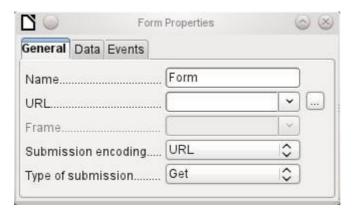

Figure 26: Context menu for form

# Form properties

When the form properties are called up using the context menu in the Form Navigator or the context menu of a form control, a Form Properties window appears. It has three tabs: **General**, **Data** and **Events**.

#### General tab

Here you can change the Name of the form. In addition there are design possibilities that have no significance inside Base. They show only the more general possibilities for design using a form editor; when you create a Web form you will need to use them.

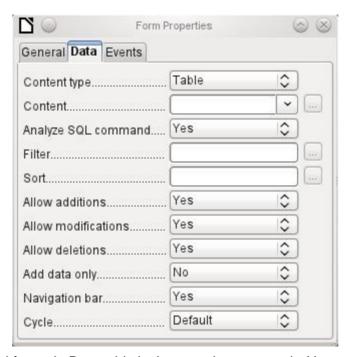

URL: Destination for the data.

Frame: Section of the destination website to be addressed where necessary.

Submission encoding: in addition to the normal character encoding for transmission to the URL, you can specify here text encoding and multipart coding (for example, for transfer of data).

*Type of submission*: GET (visible via the URL attached to the filename; you can see this often in the web if you use a search engine) or POST (not visible; suitable for large data volumes).

## Data tab

For creating internal forms in Base, this is the most important tab. Here you can set the following initial properties for the form:

Content type: Choose between Table, Query and SQL command. While Table can always be used for data entry into a form, this is not always the case for Query (for more information, see Chapter 5, Queries, in this book) or direct entry of a SQL command. Here we are dealing with a query that is not visible in Base's query container but has in principle the same structure.

Content: According to whether Table or Query was chosen above, all available tables and queries are listed. If a SQL command is to be created, you can invoke the Query Editor by using the button with the three dots to the right of the Content field.

Analyze SQL command: If the analysis of SQL commands should not be permitted (because, for example, you are using code that the GUI cannot show correctly), you should choose **No** here. However this will prevent the form accessing the underlying data using a filter or a sort.

*Filter*: Here you can set a filter. To get help with this, click the button to the right of the field. See also Chapter 3, Tables, in this book.

*Sort*: Here you can set up a Sort for your data. To get help, click the button to the right of the field. See also Chapter 3, Tables.

Allow additions: Should the entry of new data be allowed? By default this is set to Yes.

Allow modifications: Should editing of the data be allowed? By default also Yes.

Allow deletions: The deletion of data is also allowed by default.

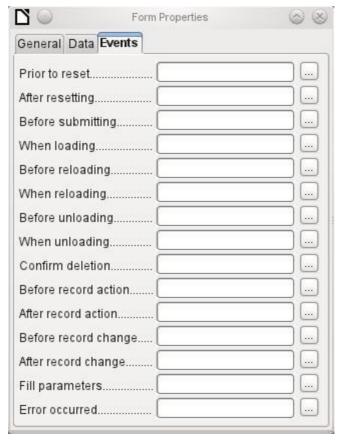

Add data only: If you choose this option, an empty form will always be displayed. There will be no access to existing data, which can neither be edited nor viewed.

Navigation bar: The appearance of the Navigation Bar at the bottom of the screen can be switched on or off. There is also a possibility, when you have a subform, always to show the Navigation Bar for the main form, so that activation of this toolbar affects the main form only. This setting for the Navigation Bar is not relevant to the internal navigation toolbar that can be added as a form control if required.

Cycle: The Default option for Base databases is that after entry into the last field in a form, the Tab key takes you to the first field of the next record – that is, a new record will be created. For

databases, this has the same effect as *All records*. By contrast, if you choose *Active record*, the cursor will move only within the record; when it reaches the last field, it will jump back to the first field in that record. *Current page* refers particularly to HTML Forms. The cursor jumps from the end of a form to the next form on that page further down.

#### **Events tab**

**Events** can trigger macros. A click on the button on the right (...) allows macros to be linked to the event.

Reset: The form is emptied of all new entries that have not yet been saved.

Before submitting: Before the form data are sent. This is only meaningful for Web forms.

When loading: Only when opening the form. Not when loading a new record into the form.

*Reloading*: This takes place when the content of the form is refreshed, for example by using a button on the Navigation Bar.

*Unloading*: This option seems not to function. It would be expected to refer to the closing of the form.

Record action: This includes, for example, storage using a button. In tests, this action regularly duplicates itself; macros run twice in succession.

Record change: The opening of a form counts as a record change. Whenever one record changes to another within the form, this action likewise occurs twice. Macros are therefore run twice in succession.

*Fill parameters:* This macro will be run if a parameter query is to be invoked in a subform, but for some reason the parameter is not correctly transmitted from the main form. If this event is not caught, a parameter query will follow the loading of the form.

Error occurred: This event could not be reconstructed.

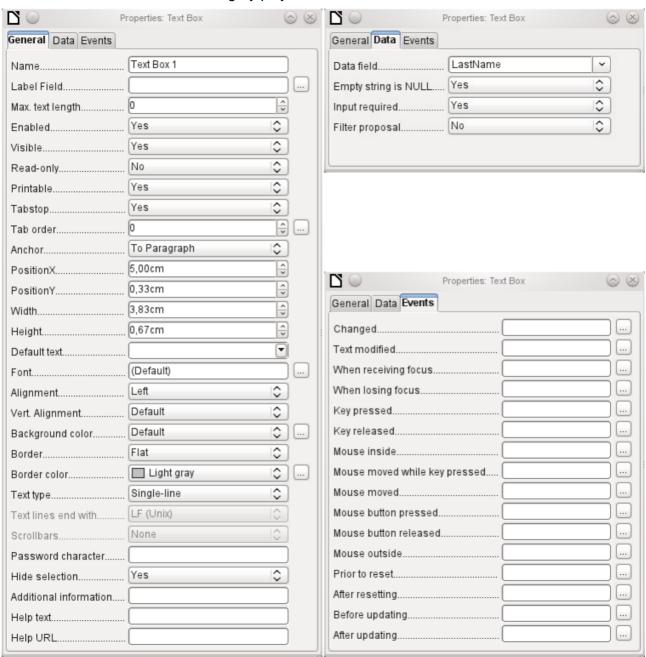

# **Properties of controls**

Once a form has been created, it can be filled with visible controls. Some controls allow the content of the database to be displayed, or data to be entered into the database. Other controls are used exclusively for navigation, for searching, and for carrying out commands (interaction). Some controls serve for additional graphical reworking of the form.

Data entry and Data display			
Control	Use		
Text field	Text entry		
Numeric field	Entering numbers		
Date field	Entering dates		
Time field	Entering times		
Currency field	Numeric entry, preformated for currency		
Formatted field	Display and entry with additional formatting, for example using measurement units		
List box	Choosing between several different possibilities, also for transfer into the database of values other than those displayed		
Combo box	Similar to a list field, but with only the displayed value transferred, or you can enter new values by hand		
Check box	Yes/No Field		
Options button	Radio button; allows you to choose from a small number of possibilities		
Image control	Display of images from a database and entry of images into a database via a path selection		
Pattern field	Entry into a preset mask; limits the entry possibilities to specific character combinations		
Table control	Universal entry module, which can display a whole table. Integrated into this control are many of the above controls		
Design			
Control	Use		
Label field	Heading for the form, description of other controls		
Group box	A frame around, for example, a set of option buttons		
Interaction			
Control	Use		
Button	Button with label		
Image Button	Like a button, but with an additional graphic displayed on it		
Navigation bar	Toolbar very similar to the one at the bottom edge of the screen		
File selector	For selecting files, for example to upload in an HTML form—not further described		
Spin box	Can only be used with a macro—not further described		
Scrollbar	Can only be used with a macro—not further described		

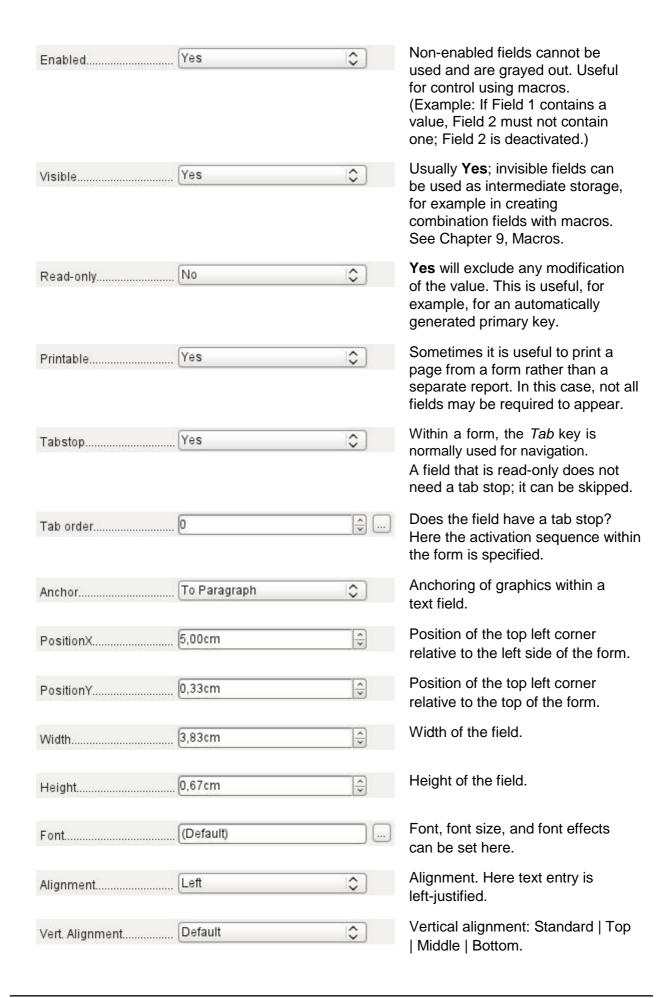

## Default settings for many controls

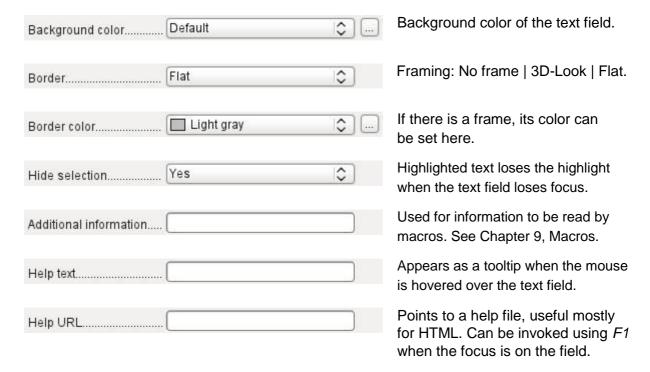

As with forms, properties are grouped into three categories: General, Data and Events. General comprises everything that is visible to the user. The data category specifies the binding to a field in the database. The Events category controls actions, which can be bound to some macro. In a database without macros, this category plays no role.

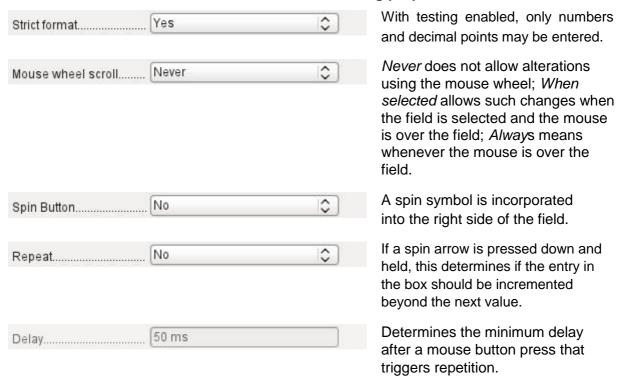

#### General tab

Name	Text Box 1	The name of a control must be unique within the form—used for access using macros.
Label Field		 Does the field have a label? This groups field and label together.

## In addition, numeric, date fields, etc have the following properties.

## Data tab

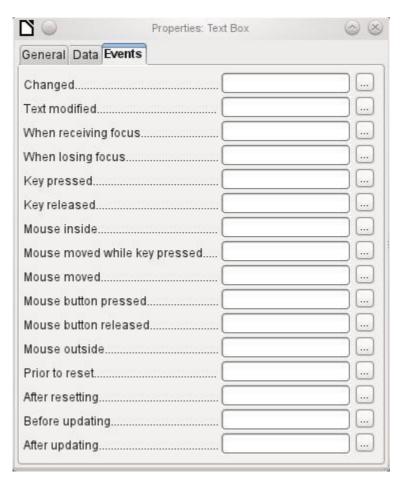

Data field: Here you create the binding with the table on which the form is based.

*Empty string is NULL*: Whether an empty string should be treated as (NULL) or the content simply deleted.

Entry required: This condition should match the one in the table. The GUI will prompt for entry if the user has not entered a value.

*Filter proposal*: When the data is to be filtered, the content of this field is temporarily stored as a suggestion. Caution – with large contents, this choice can use a lot of storage.

#### **Events tab**

Changed: This event takes place when a control is modified and afterwards loses the focus.

*Text modified*: Refers to the content, which can in fact be text, numeric, or whatever. Occurs after each additional character is entered.

When receiving focus: The cursor enters the field. Under no circumstances must the macro create a message dialog on the screen; clicking in such a dialog causes the form field to lose the focus and then recover it, triggering the macro again. A loop is created which can only be broken by using the keyboard.

When losing focus: The cursor leaves the field. This can lead to the same kind of interplay when the handling of the event causes it to recur.

*Key*: Refers to the keyboard. For example, a key is pressed when you move through the form using the Tab key. This causes a field to receive the focus. Then the key is released.

*Mouse*: Self-explanatory; These events only takes place if the mouse is or was already within the field ("outside" corresponds to the javascript onMouseOut).

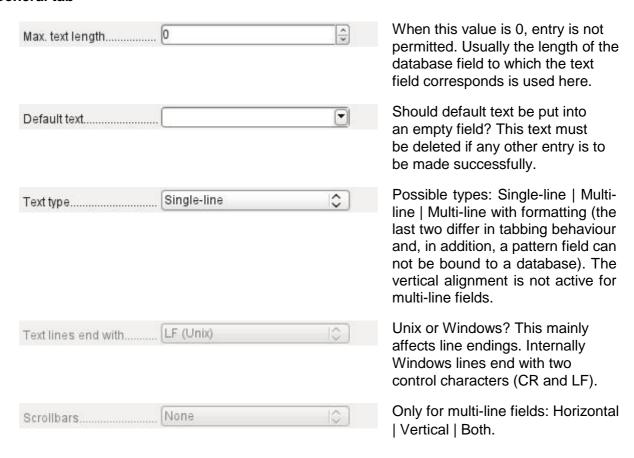

Reset: The form is emptied of all data. This happens, for example, when starting a new record. When a form is first loaded, the two events *Prior to reset* and *After resetting* occur in succession, before the form is available for input.

*Updating*: If the event is bound to a form control, update takes place when the focus is lost and jumps to another form control, after altering the content of the field. Changes in the form are accepted and displayed. When a form is closed, the two events *Before updating* and *After updating* occur in succession.

## Text field

As well as the properties set out on page 70, text fields can have the following additional properties:

#### General tab

Password character	Active only for single-line fields
Auto Antis Avertidar notice Sustained von de Done des Best Long 14 -	Changes characters to see only
	points.

#### Data tab

Nothing of significance.

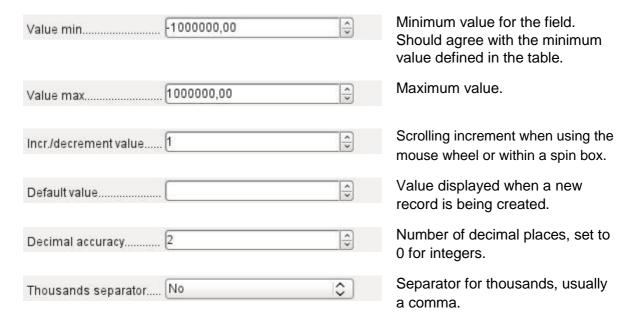

#### **Events tab**

Nothing of significance.

## Numeric field

In addition to properties already described, the following properties exist:

#### **General tab**

## Data tab

There is no check on whether a field can be NULL. If there is no entry, the field will be NULL and not 0.

No filter proposal is offered.

## **Events tab**

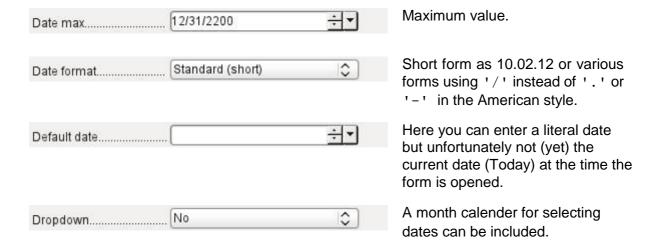

The "Changed" event is absent. Changes must be handled using the "Text modified" event (the word text is not to be taken literally here).

## Date field

As well as the properties described on page 70, the following are to be noted.

## General tab

#### Data tab

There is no check on whether a field can be NULL. If there is no entry, the field will be NULL and not 0.

No filter proposal is offered.

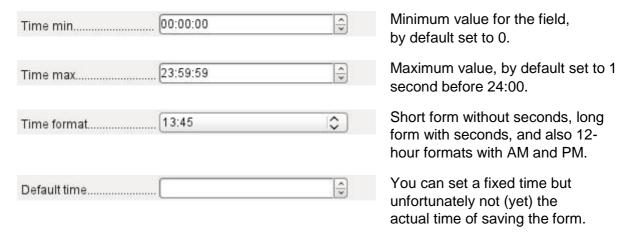

## **Events tab**

The "Changed" event is absent. Changes must be handled using the "Text modified" event (the word text is not to be taken literally here).

## Time field

As well as the properties listed on page 70, the following features are

## available. General tab

## Data tab

There is no check on whether a field can be NULL. If there is no entry, the field will be NULL and not 0.

No filter proposal is offered.

## **Events tab**

The "Changed" event is absent. Changes must be handled using the "Text modified" event (the word text is not to be taken literally here).

## **Currency field**

In addition to the properties already listed on page 70, the following features are available:

#### **General tab**

Min. value, Max. value, Increment, Default value, Decimal places, and Thousands separator. correspond to the general properties listed on page 75. In addition to these, there is only:

#### Data tab

There is no check on whether a field can be NULL. If there is no entry, the field will be NULL and not 0.

No filter proposal is offered.

#### **Events tab**

The "Changed" event is absent. Changes must be handled using the "Text modified" event (the word text is not to be taken literally here).

## Formatted field

In addition to the properties listed on page 70, the following features are offered:

#### General tab

Minimum and maximum values, and the default value, depend on the formatting. Behind the button for Formating is a flexible field that makes most currency and numeric fields unnecessary. Unlike a simple currency field, a pattern field can show negative sums in red.

Among the numeric formats can be seen, alongside Date, Time, Currency or normal numeric format, possibilities for using fields with a measurement unit such as kg (see Figure 27). See also the general Help on numeric format codes.

#### Data tab

Nothing special to report.

#### **Events tab**

The "Changed" event is absent. Changes must be handled using the "Text modified" event (the word text is not to be taken literally here).

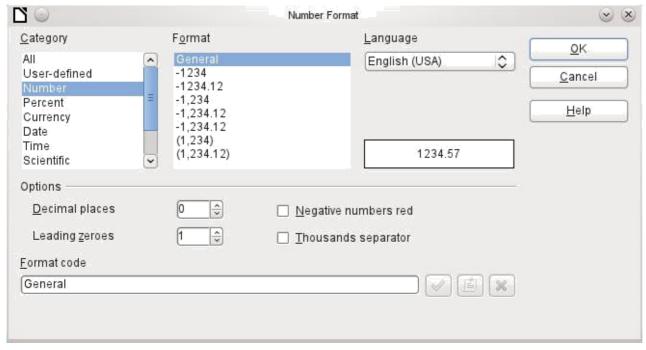

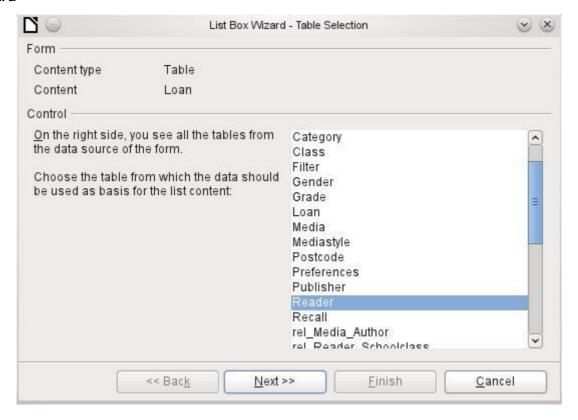

Figure 27: Formatted field with general numeric options

## List box

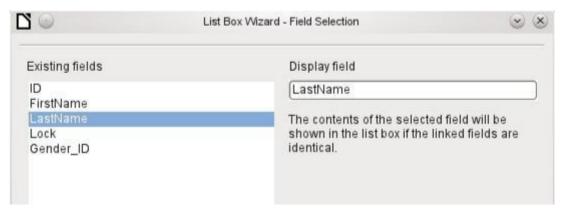

When a list box is created, the List Box Wizard appears by default. This automatic appearance can be switched off if required using the Wizards On/Off button (shown in Figure 24).

#### Wizard

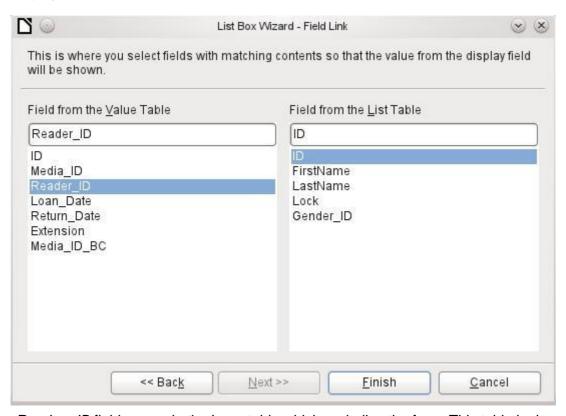

The form is already defined. It is bound to a *Table* named Loans. A list box shows the user different data from what is actually transmitted into the table. This data usually comes from another table in the database, and not from the table to which the form is bound.

The Loans table is supposed to show which Reader has borrowed which Media. However this table does not store the name of the reader but the corresponding primary key from the Reader table. It is therefore the Reader table that forms the basis for the list box.

The *Surname* field from the Reader table should be visible in the list box. This serves as the Display field.

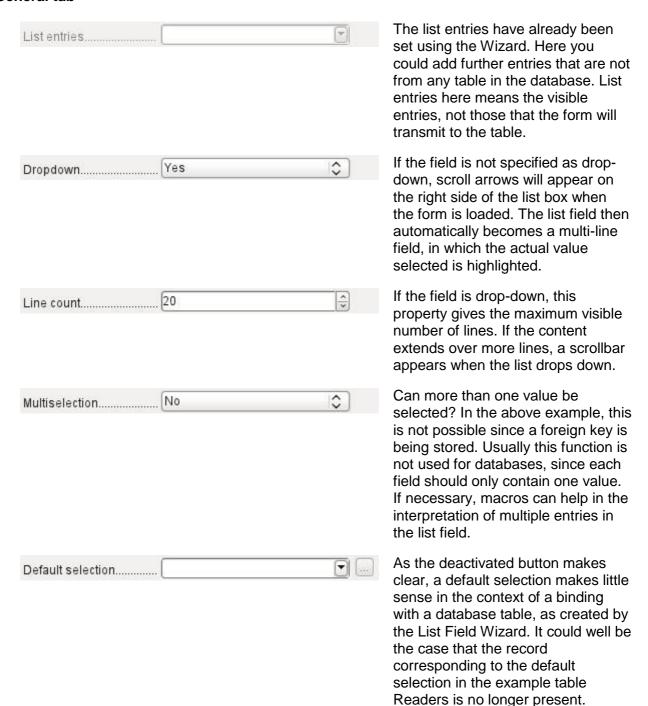

The Reader\_ID field occurs in the Loan table which underlies the form. This table is described here as the Value table. The primary key ID from the Reader table must be bound to this field. The Reader table is described here as the List table.

The list box has now been created complete with data and default configuration and is fully functional.

In addition to the properties listed on page 70, the following features are available.

## General tab

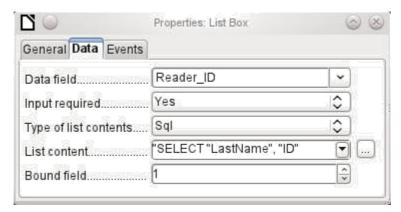

#### Data tab

In addition to the usual data properties *Data field* and *Input required*, there are significant properties which affect the binding between the displayed data and the data to be entered into the table that underlies the form.

Type of list contents: Valuelist | Table | Query | SQL | SQL [Native] | Tablefields

List contents Valuelist: If list entries have been created under **General**, the corresponding values to be stored are entered here. The list contents are loaded with individual items separated by **Shift** - **Enter**. The List content field then shows them as "Value1"; "Value2"; "Value3" ... The Bound Field property is inactive.

List contents Table: Here one of the database tables can be selected. However this is seldom possible as it requires the content of the table to be so structured that the first table field contains the values to be displayed in the list field, and one of the following fields contains the primary key which the table underlying the form uses as a foreign key. The position of this field within the table is specified in *Bound Field*, where the **Numbering begins with 0 for the first field of the database table**. But this 0 is reserved for the displayed value, in the above example the Surname, while the 1 refers to the ID field.

List contents Query: Here a query is first created separately and stored. The creation of such queries is described in Chapter 5, Queries. Using the query, it is possible to move the ID field from the first position in the underlying table to the second position, here represented by the bound field 1.

*List contents SQL*: The List Box Wizard fills this field. The query constructed by the Wizard looks like this:

The query is the simplest possible. The Surname field occurs at position 0, the ID field at position 1. Both are read from the Reader

table. As the bound field is Field 1, this SQL formula works. Here should be added ORDER BY "LastName" ASC. So you haven't to scroll to long through the list to find somebody. An additional problem might be, that LastName could be the same for more than one reader. So FirstName must be added in the view of the list box. When there are readers with the same LastName and the same FirstName, the primary key ID must also be shown. See Chapter 5, Queries, for information on how this works.

List contents SQL [Native]: The SQL formula is entered directly, not using the Wizard. Base does not evaluate the query. This is suitable when the query contains functions that might perhaps not be understood by the Base GUI. In this case the query is not checked for errors. More about **direct SQL Mode** can be found in Chapter 5, Queries.

List contents tablefields: Here Field names from a table are listed, not their content. For the Reader table, the List contents would be "ID", "Given name", "Surname", "Lock", "Gender ID".

#### **Events tab**

In addition to the standard events, the following events are available:

Execute action: If a value is chosen by the keyboard or the mouse, the list box executes this action.

*Item status changed*: This could be the change of the displayed content of a list box through the use of the drop-down button. It could also be a click on the drop-down button of the field.

*Error occurred*: Unfortunately, this event cannot be reconstructed for list boxes.

#### Combo box

As soon as a combo box is created, a Wizard appears by default, just as with a list box. This automatic behavior can be switched off if necessary using the Wizards On/Off button (see Figure 24).

Combo boxes write the selected text directly into the table underlying the form. Therefore the following example shows both the table linked to the form and the one selected for the control as the Reader table.

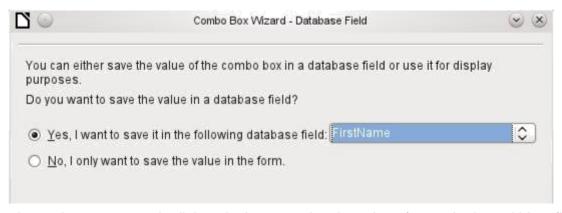

#### Wizard

Again the form is predefined, this time with the Reader table. As the data to be displayed in the combo box is also to be stored in this table, the source selected for the data for the list is likewise the Reader table.

In the Reader table the FirstName field occurs. This should be displayed in the combo box.

In a database, there seems to be little point in not storing the value of a combo box within a field. We want to read given names from the Reader table, and also to make them available for new readers, so that new records do not need to be created for a given name that already exists in the database. The combo box shows the first name, and text input is not necessary.

If a new value does need to be entered, this can be done easily in a combo box, as the box shows exactly what is going into the underlying table for the form.

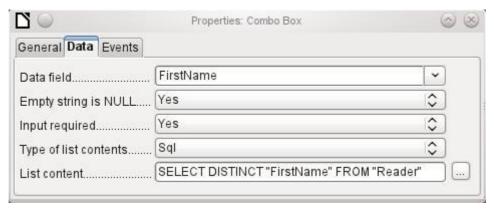

In addition to the properties shown on page 70 and described for list boxes, the following features are available.

#### General tab

During entry of new values, a list of matching values (if any) is displayed for possible selection.

## Data tab

The data fields conform to the existing default settings and the settings for a list box. The SQL command however shows a special feature:

```
SELECT DISTINCT "FirstName" FROM "Reader"
```

Adding the **DISTINCT** keyword ensures that duplicate given names are shown only once. However, creation using the Wizard once more makes it impossible for the content to be sorted.

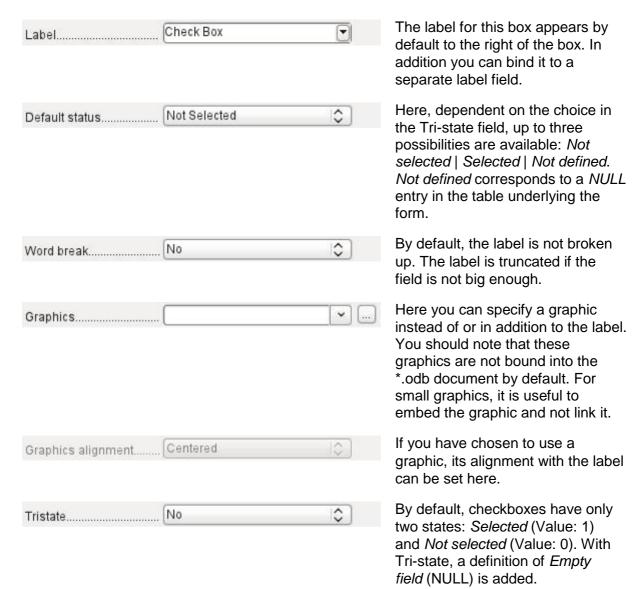

## **Events tab**

The events correspond to those for a list box.

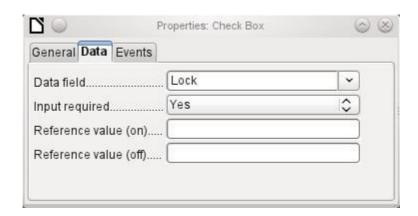

#### Check box

The check box appears immediately as a combination of a check box field and a label for the box. In addition to the properties described on page 70, the following features are available.

## **General tab**

#### Data tab

The check box can be given a reference value. However only the values of 1 (for On) or 0 (for Off) can be transferred to the underlying data field (check boxes act as fields for the choice of Yes and No).

#### Events tab

The fields "Changed", "Text modified". "Before updating" and "After updating" are all absent.

Additional fields for a check box are "Execute action" (see List box) und "Item status changed" (corresponds to "Changed").

## **Option button**

The option button is similar to the check box described above, except for its general properties and its external (round) form.

When several option buttons in the form are linked to the same table field, only one of the options can be selected.

#### General tab

addressed.

#### Data tab

See under Check box. Here, however, reference values that are entered are actually transferred to the data field.

## **Events tab**

See under Check box.

## Image control

A image control handles the entry and display of graphical material in the database. The underlying data field must be a binary field.

Entry into a image control takes place either by a double-click with the mouse to open a file selection dialog, or a right-click to choose whether an existing graphic is to be deleted or replaced.

A graphical control by default has no Tab stop.

In addition to the properties described on page 70, the following features are available.

## **General tab**

No: The image will not be fitted to the field. If it is too big, the field will show a window into the image. The image is not distorted.

*Keep ratio*: The image is fitted to the control but not distorted (aspect ratio preserved).

Autom. Size: The image is fitted to the control and may be shown in a distorted form.

## Data tab

Nothing further to report.

## **Events tab**

The events "Changed", "Text modified", "Before updating" and "After updating" are missing..

#### Pattern field

An input mask is used to control input into the field. Characters are pre-specified for particular positions, determining the properties of entered characters. The preset characters are stored along with the entered ones.

In addition to the properties described on page 70, the following features are

#### available. General tab

Edit mask	This determines what characters can be entered.
Literal mask	This is what the form user sees.

The following content is taken from LibreOffice Help:

The length of the edit mask determines how many characters may be entered. If the user's entry does not match the mask, the entry is rejected on leaving the control. The following characters are available for defining the edit mask.

Character	Meaning
L	A text constant. This position cannot be edited. The actual character is displayed
	at the corresponding position in the literal mask.
а	Represents any of the letters a-z/A-Z. Capital letters are not converted into lower
	case.
Α	Represents any of the letters A-Z. If lower-case letters are entered, they will
	automatically be converted to upper case.
С	Represents any of the characters a-z/A-Z plus the digits 0-9. Capital letters are
	not converted into lower case.
С	Represents any of the letters A-Z plus the digits 0-9. If lower-case letters are
	entered, they will automatically be converted to upper case.
N	Only the digits 0-9 can be entered.
х	All printable characters are allowed.
Х	All printable characters are allowed. If lower-case letters are entered, they will
	automatically be converted to upper case.

So, for example, you can define the literal mask as "\_\_/\_\_/2012" and the edit mask as "NNLNNLLLLL", to allow the user to enter four characters only for a date.

#### Data tab

Nothing further to report.

#### **Events tab**

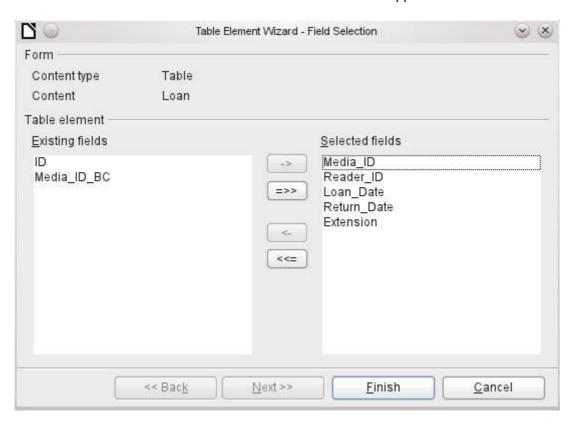

The "Changed" event is absent.

#### Table control

This is the most comprehensive control. It provides a table, which can then be provided with controls for individual columns. This not only allows the actual data to be viewed during input, but also the previously entered data, without the need to use the Navigation bar to scroll through the records.

Not every field that is possible in a form can be selected for a table control field. Push buttons, image buttons and option buttons are not available.

The Table Control Wizard assembles in a window the fields that will appear afterwards in the table.

In the control the Loans table is available for editing. In addition to the ID (primary key) field and the Media\_ID\_BC field (entry of media using a bar-code scanner), all fields are to be used in the control.

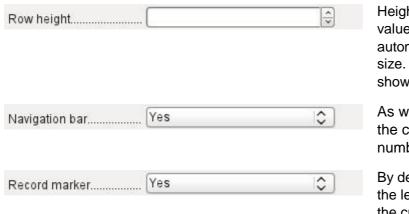

The previously created table control must now be further developed, to allow entry into the Loans table. For fields such as *Reader\_ID* or *Media\_ID*, it would be more useful to be able to choose the reader or the media directly, rather than a number representing the reader or media. For this purpose, controls such as list boxes can be placed within the table control. This is declared later. The formatting of the *Extension* field with two decimal places was certainly not intended.

Figure 28: Output of the Table Control Wizard

In addition to the properties listed on page 70, the following features are available.

## General tab

Height of individual lines. With no value here, the height is automatically adjusted to the font size. Multi-line text fields are then shown as single lines to be scrolled.

As with tables, the lower edge of the control shows the record number and navigation aids.

By default there is a record marker on the left edge of the control. It indicates the current record. You can use the record marker to access the delete function for the whole record.

#### Data tab

Since this is a field that contains no data itself but manages other fields, there are no data properties.

## **Events tab**

The "Changed" and "Text modified" events are missing. The "Error occurred" event is added.

## Label field

In addition to the properties described on page 70, the following features are

## available. General tab

By default a label is not wrapped. If it is too long for the field, it is truncated. Caution: word wrapping does not recognize spaces, so if the field is too small, a break can occur within a word.

## Data tab

None.

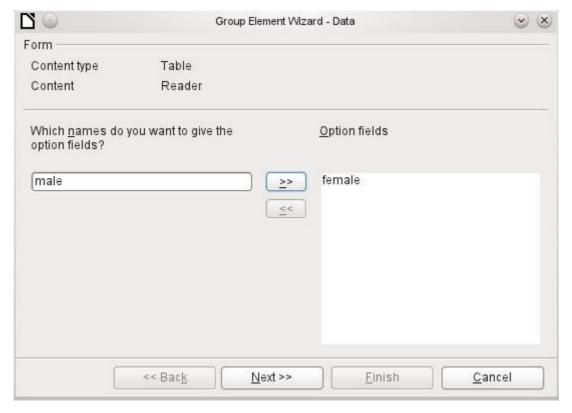

## **Events tab**

The label field reacts only to events that are connected with the mouse, a key or the focus.

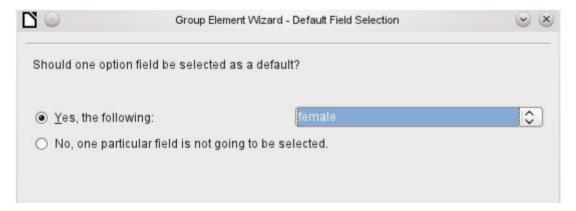

## **Group box**

A group box graphically groups several controls and provides them with a collective label.

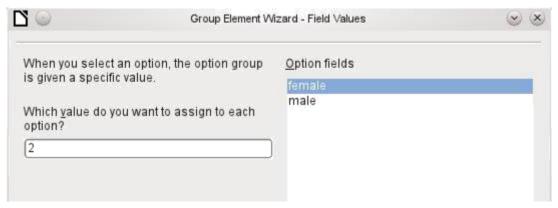

If a group box is created with Wizards active, the Wizard proceeds from the assumption that several option buttons will occur together within this frame.

This form is based on the Reader table. We are dealing with the choice of gender. The entries are the labels of the option buttons.

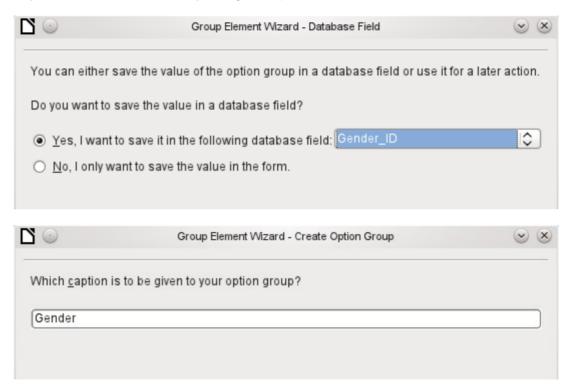

Here the default option is "female". If there is to be no default field, the default entry in the underlying table is *NULL*.

The Wizard gives the option buttons separate values by default, here 1 for female and 2 for male. These values correspond to the examples of primary key fields in the Gender table.

The value selected by clicking an option button is transferred to the *Gender\_ID* field of the form's underlying table Readers. In this way the Readers table is provided with the corresponding foreign key from the Gender table by using the option button.

The option button group is given a group box (frame) with the label Gender.

If female is selected in the active form, male is deselected. This is a characteristic of option buttons that are bound to the same field in the underlying table. In the example shown above, the option buttons replace a two-element list box.

In addition to the properties described on page 70, the following features are available.

## General tab

The label can be changed from its default value. At present the frame properties (Line thickness, line color) cannot be changed but you can change the font formatting.

#### Data tab

None, since this control serves only for visual grouping of fields.

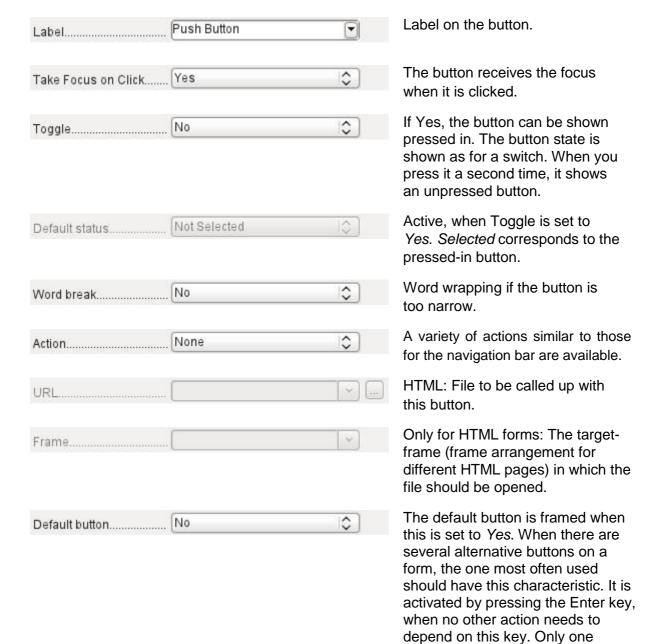

#### **Events rab**

The group box reacts to events involving the mouse, a key, or the focus.

## Push button

In addition to the properties described on page 70, the following features are

## available. General tab

Chapter 4 Forms 91

button on the form can be the

default button.

## Data tab

None. A button only carries out actions.

#### **Events tab**

"Approve action", "Execute action" and "Item status changed".

## Image button

In addition to the properties already described on page 70, the following features are available.

#### General tab

Similar to a normal button. However this button has no text and the button itself is not visible. You see only a frame around the graphic.

By default, an image button has no tab stop.

Caution: at the time of writing, hardly any actions work with this button. It is practically only usable with macros.

#### Data tab

None; this control only carries out actions.

#### **Events tab**

"Approve action" and all events involving the mouse, a key, or the focus.

## Navigation bar

Figure 29: Navigation bar control

The standard Form Navigation bar is inserted into forms at the lower edge of the screen. The insertion of this toolbar can cause a brief rightward shift of the form as it builds up on the screen. This can be distracting in cases where the navigation bar is switched off again for some parts of the visible form, for example when there are subforms or more than one form in the visible form.

By contrast, a navigation bar control that is part of the form, separate from the corresponding items, makes it clear through which items you navigate with the toolbar. The form for Loans, for example, needs to search first through the readers and then show the media loaded to the reader. The navigation bar control is positioned near the reader, so the user notices that the navigation bar is used for the reader and not for the media loaned to the reader.

The standard Form Navigation bar makes available the buttons shown in Figure 30. The navigation bar control shows the same buttons except those for Find Record, Form-Based Filters and Data source as Table.

Figure 30: Navigation buttons

In addition to the properties listed on page 70, the following features are available for the Navigator Bar control.

## **General tab**

The icon size is adjustable. In addition you can choose which groups are displayed. These are shown in Figure 29 from left to right using a vertical line as a group separator: Positioning, Navigation, Acting on a record, and groups of commands for Filtering and Sorting.

#### Data tab

None, as this control only carries out actions.

## **Events tab**

All events that involve the Mouse, a key, or the focus.

Independent of this form control, the **insertable navigation bar** naturally continues to exist with the same items as the above figure.

This insertable navigation bar provides additionally the *general record search*, the *form-based filter* and the display of the form's underlying *data source in table view* above the form.

If you are working not just with a form but with subforms and ancillary forms, you must be careful that this insertable navigation bar does not disappear as you switch forms. That creates a disturbing effect on the screen.

## Multiple selection

If you use the Select icon (Figure 24) to select a large region or several elements of a form, the following modifications may be carried out (see Figure 31).

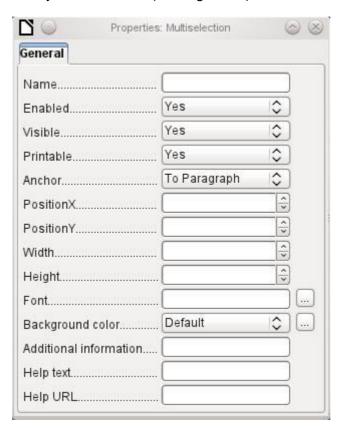

Figure 31: General properties of form fields in a multiple selection

You should not alter the name. That would cause all the selected elements suddenly to acquire the same name. It would make finding individual elements using the Form Navigator difficult, and management of the form by using named controls in macros impossible.

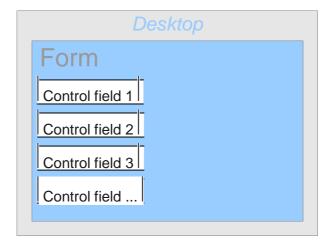

Multiple selection is more useful for changing the font, the height or the background color of controls. Note that changing the background color affects the labels as well.

If you want to alter only the labels, hold down the *Control* key and click these controls directly or in the Navigator, or right-click on a field to call up the control properties. Now the choice of properties that you can change is greater as you are dealing only with similar fields. You can change anything here that is available in a label field.

The possibilities of multiple selection depend therefore on the choice of fields. You can simultaneously change controls of the same kind that have all the properties that exist for a single instance.

## A simple form completed

A simple form has form controls for writing or reading records from a single table or query. Its construction is shown by the following example.

The example of a simple form for library loans is shown here using several variants. The quick way to use the Form Wizard is described in Chapter 8, Getting Started with Base, in the *Getting Started with LibreOffice* guide. Here we describe the creation in Design View.

The heading for the form was created using a label field. The font was changed. The label field is anchored to a paragraph in the top left corner of the document. Using the context menu of the label field, a form was created that was linked to the Loans table (see "Form properties" on page 66). The page has also been given a uniformly colored background.

## Adding groups of fields

A quick variant for direct entry of fields with labels is to use the *Add Field* function.

This function, available on the Formula Design toolbar (see Figure 22), allows all fields of the underlying table to be selected.

Double-click on the fields to insert them into the form as a group with labels (unfortunately all on the same spot). The group needs to be separated out so that the form eventually looks like the following illustration. For a better view, all unnecessary toolbars have been removed from the window, which has also been compressed so that not all elements of the Navigation bar are visible.

All fields have been selected except *Media\_ID\_BC*, which is designed to be used only with a barcode scanner.

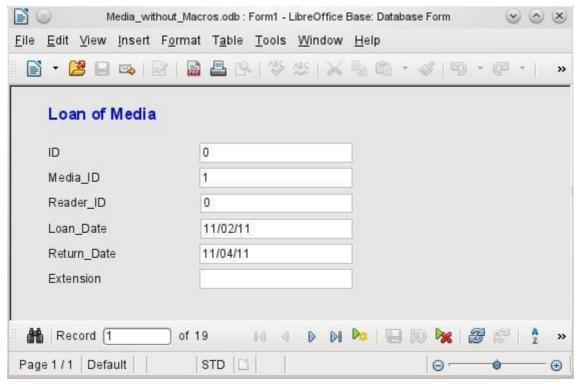

Figure 32: Simple form made by using Add Field

For each table field, an appropriate form control has been automatically selected. Numbers are in numeric fields and are declared as integers without decimal places. Date fields are represented correctly as date controls. All fields have been given the same width. If a graphical control had been included, it would have been given a square field.

## Adjusting field proportions

We can now do some creative things, including adjusting the length of the fields and making the dates into drop-down fields. More important still is for the *Media\_ID* and the *Reader\_ID* fields to be made more user -friendly, unless every library user has a library ID card and every medium is supplied with an ID on accession. That will not be assumed in what follows.

To adjust individual fields, we must edit the group. This can be done with a right-click on the group and then following the context menu (Figure 33). For future work, it will be clearer if we use the Form Navigator.

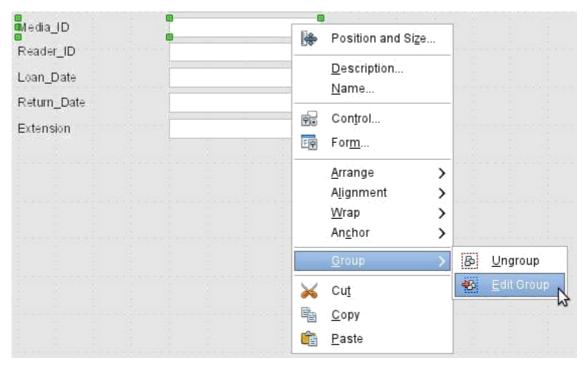

Figure 33: Form controls: editing the group

The Form Navigator displays all the elements of the form with their labels. For controls, the names are taken directly from the names of the fields in the underlying table. The names of the labels have the suffix *Label*.

A click on *Media\_ID* selects this field (Figure 34). Right-click to replace the selected field with a different type of field, using the context menu (Figure 35).

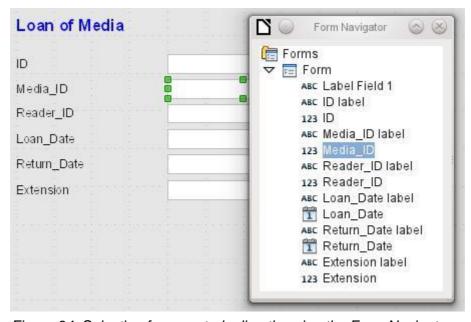

Figure 34: Selecting form controls directly using the Form Navigator

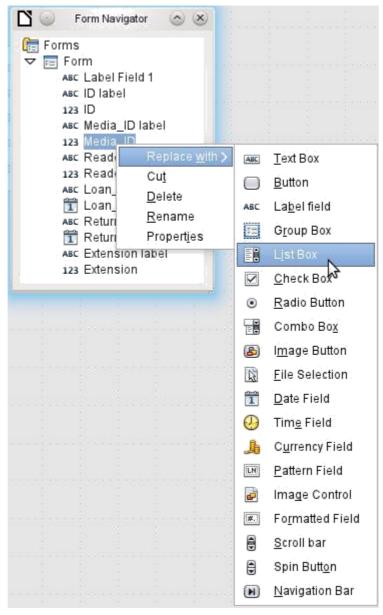

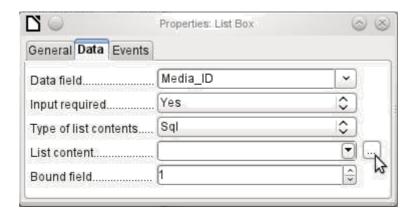

Figure 35: Replacing one kind of control by another using the Form Navigator

This replacement is carried out for the *Media\_ID* and *Reader\_ID* controls.

The change is made visible in the Form Navigator by the change in the accompanying icon.

The SQL query for the list field can now be created through the graphical user interface by clicking on the button at the right. This is carried out automatically when a list box is created directly, but not when it is formed by conversion from another type of control. For the SQL command, see Chapter 5, Queries.

Since the list boxes are to be made drop-down, the following defects can be corrected at the same time:

- The labels for the list boxes should be *Media* instead of *Media\_ID* and *Reader* instead of *Reader ID*.
- The *ID* control should be declared as read-only.
- Any fields which are not absolutely necessary for issuing loans for a new medium do not need a tab stop. Without it, the form can be traversed much faster. If necessary, the tab stop can also be adjusted using the activation sequence (see page 70). Only the *Media, Reader* and *Loan date* fields must be accessible in all cases using the *Tab* key.
- If the form is intended for carrying out loans, it is unnecessary and also confusing for
  returned media to be displayed. Media with a return date should be filtered out. In addition,
  the display order could be sorted by Reader, so that media on loan to the same person are
  displayed successively. See the note on "Form properties" on page 66. However there is a
  problem here in that readers can be sorted only by ID, not alphabetically, because the
  table underlying the form only contains the ID.

## Adding single fields

The addition of single fields is a bit more complicated. The fields must be selected, dragged onto the form surface, and the appropriate field from the underlying table specified. In addition, the type of field must be correctly chosen; for example, numeric fields have two decimal places by default.

Only when creating list boxes does the Wizard come into play, making it easier for a novice to carry out the steps for creating correct fields—up to a point. Beyond that point, the Wizard ceases to meet requirements because:

- The entries are not automatically sorted.
- Combining several fields in the list box content is not possible.

Here again we need to make retrospective improvements, so that the required SQL code can be created quite quickly using the built-in query editor.

When adding single controls, the field and its label must be explicitly associated (see "Default settings for many controls" on page 70). In practice it could be better if you do not associate fields with the labels. So you must not choose **Edit Group** before changing the properties of a field.

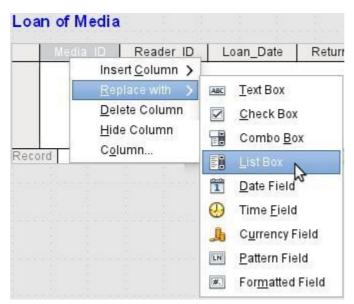

## Table control

The use of the Table Wizard to create a table control has already been described on page 87. It has however some defects which need to be improved:

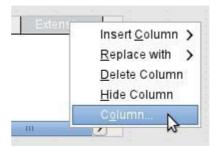

- The Media\_ID and Reader\_ID fields must become list boxes.
- Numeric fields must be stripped of their decimal places, since the Wizard always specifies two decimal places for numbers.

Changing fields within the table control is not possible using the same method as described for other controls. In the Navigator, the description of fields ends with the table control. The Navigator knows nothing about the controls that lie within the table control, referring to fields in the underlying table. This equally applies later, when attempts are made to access the fields using macros. They cannot be accessed by name.

The controls within the table control are called columns. Using the context menu, it is now possible to replace one type of field by another. However the whole range of types is not available. There are no push buttons, option boxes, or graphical controls.

The properties of the fields are hidden in the context menu behind the concept of columns. Here, for example, the numeric field *Extension* can be changed so that no decimal places are shown.

Also the default minimum value of -1,000,000.00 hardly makes sense for a loan extension. The number should always remain small and positive.

As soon as the properties of a column are called up, you can select another column without shutting the properties dialog. In this way you can work on all the fields, one after another, without having to save in between.

End by saving the entire form, and finally the database itself.

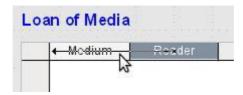

The properties of the fields built into a table control are not so comprehensive as for those outside. The font, for example, can be set only for the entire table control. In addition, you do not have the option of skipping individual columns by removing their tab stops.

Tip

You can move through a form using either the mouse or the *Tab* key. If you tab into a

table control, the cursor will move one field to the right for each additional tab; at the end of the line, it will move back to the first field of the next record in the table control. To exit the table control, use *Ctrl+Tab*.

The order of the columns can be changed by dragging the column header:

If this is done in form design view, it is permanent. A temporary change in order can be carried out during data entry by using the same method.

If only certain fields should be visible during use, you can use several different table controls in the form, as the *Tab* is captured by default by each table control.

The form shown in Figure 36 is for the loan of media. Only the fields immediately necessary are shown in the upper table control. The lower one shows all the fields, so that it is apparent which person and medium the return is for.

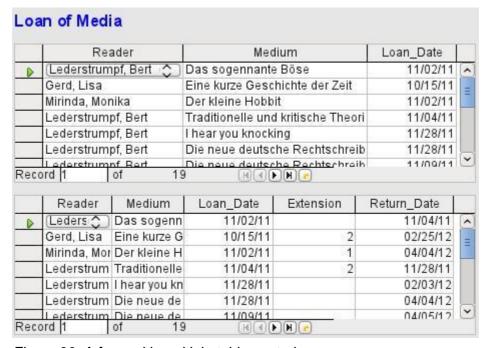

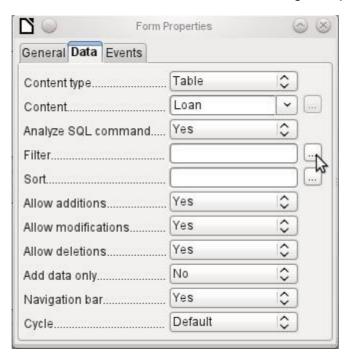

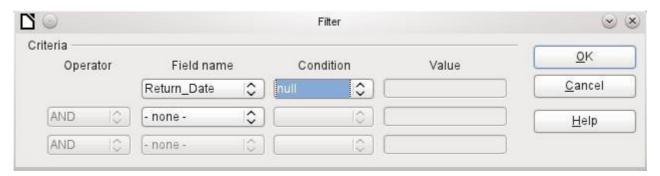

Figure 36: A form with multiple table controls

This figure shows an aesthetic failing that needs urgent attention. In the upper table control, the same medium sometimes occurs more than once. This happens because the table also shows media that have been returned earlier. Therefore the data needs to be filtered to show only the loans. Records with a return date should not appear.

This filtering is possible either by a query or directly using the form properties. If it is done using the form properties, the filter can be temporarily switched off during input. Filtering using a query is described in Chapter 5, Queries. Here we describe how to do it using form properties.

The filtering is carried out using the button with the three dots, which opens the dialog shown below. You can also enter the filter directly into the *Filter* text field if you know the SQL coding.

Using the GUI, you can now select the field named *Return\_Date*. It will show only the records for which the field is empty, where "empty" stands for the SQL designation NULL.

The cleaned-up form (shown in Figure 37) now looks rather simpler.

Of course there is still room for improvement, but compared with the earlier form, this version has a clear advantage in that all the media are visible at a glance.

The processing of data using table controls is similar to using an actual table. A right-click on the record header of an existing record causes it to be deleted, and an entry can be canceled or saved in the case of new records.

When you leave a line, the record is automatically saved.

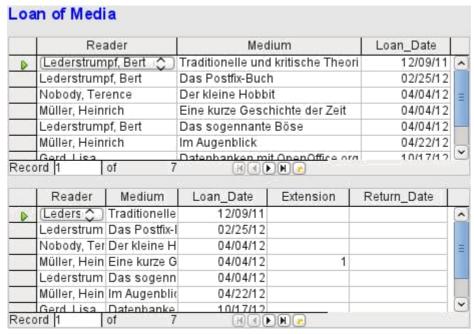

Figure 37: Amended form

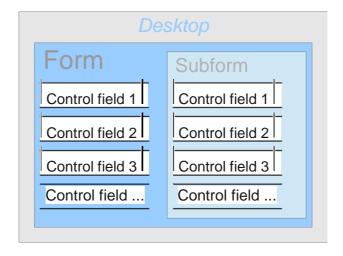

We can still improve the Loan of Media form in a number of ways.

- It would be nice if selecting a reader in one part of the form caused the media on loan to this reader to be displayed in another.
- In the table shown above, you can see a lot of records that are not necessary because
  these media are already on loan. The table was created to allow loans to be made, so
  it would be better if only an empty page appeared, which could then be filled with the
  new loan.

Such solutions are available using further forms that are hierarchically arranged and make possible separate views of the data.

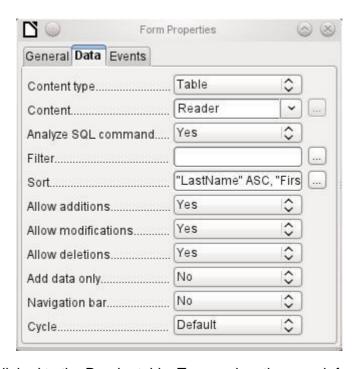

## Main forms and subforms

A subform lies within a form like a form control. Like a form control, it is bound to data from the main form. However its data source can be another table or a query (or a SQL command). The important thing for a subform is that its data source is somehow linked to the data source of the main form.

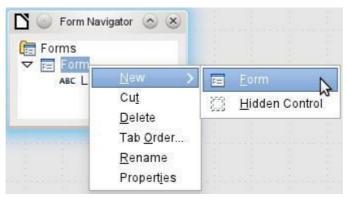

Typical table structures that lend themselves to use as subforms are tables with a one-to-many relationship (see Chapter 3, Tables). The main form shows a table with records to which many dependent records in the subform can be linked and displayed.

First we will use the relationship of the Reader table to the Loan table (see Chapter 3, Tables). The Reader table will form the basis for the main form and the Loan table will be reproduced in the sub-form.

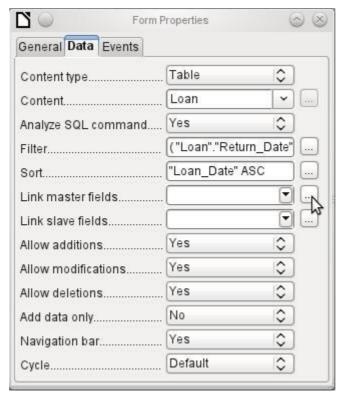

Here the main form is linked to the Reader table. To speed up the search for readers, the table is sorted alphabetically. We will do without a navigation bar, since the content of the subform would come between the main form and the navigation bar. Instead we will use the built-in form control (Figure 29).

Right-click on the main form in the Form Navigator to use the context menu to create a new form. Once again this form has the default name of Form, but it is now an element in the subfolder of the main form.

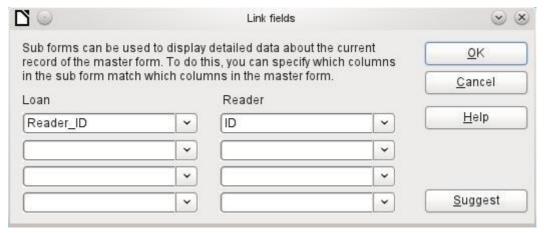

The properties of the subform must now be set up to give it the right data source, in order to reproduce the data for the correct reader.

The Loans table is chosen for the subform. For the filter we specify that the Return date field should be empty ("Return\_Date" IS NULL). This prevents any media that have already been returned from appearing. The records should be sorted by loan date. The ascending sort shows the medium on loan for the longest period at the top.

Link master fields and Link slave fields are used to create a linkage to the main form, in which the subform lies. The button with three dots shows once again that a helpful dialog is available for creating these.

Under *Loans*, the fields in the Loans table are shown, under *Readers* those of the Reader table. The *Reader\_ID* from *Loans* should be set as equivalent to the *ID* from the *Reader* table.

Although this linkage has already been created in the database using **Tools > Relationships** (see Chapter 3, Tables), the function that lies behind the Suggest button in this dialog does not reference this and would suggest that the first foreign key in the Loan table, namely *Media\_ID*,

should be linked with *ID* from the Reader table. The Form Creation Wizard solves this better by reading the relation from the relationship of the database.

The chosen link between the table for the subform and the table for the main form is now specified in terms of fields from the tables.

To create a table control for the main form, we must now select the main form in the Form Navigator. Then, if the Table Control Wizard is enabled, it will show the fields available in the main form. We deal with the subform in a similar way.

Once the table controls have been set up, we need to carry out the modifications already discussed when creating the simpler form:

- Replacing the numeric field *Media\_ID* in the subform with a list box.
- Renaming the Media\_ID field Media.
- Modifying the numeric fields to a format without decimal places.
- Limiting the minimum and maximum values.
- Renaming other fields, to save space or to add non-ASCII characters which should not be used in field names in database tables.

Sort and filter functions are supplemented for the main form by adding a navigation bar. The other fields on the navigation bar are not needed, as they are mostly available from the table control (record display, record navigation) or else carried out by movement through the table control (data storage).

The final form might look like the figure below.

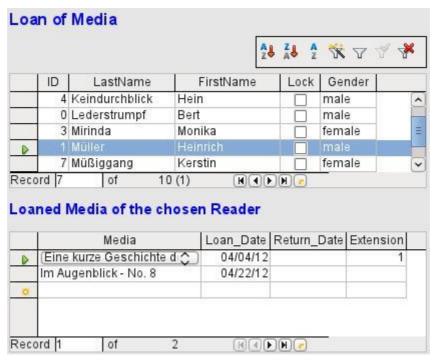

Figure 38: Form consisting of a main form (above) and a subform (below).

If a reader is now selected in the main form, the subform will show the media on loan to that reader. When an item is returned, it continues to appear on the form until the form itself is refreshed. This occurs automatically when another record is loaded into the main form. If the original reader is selected again, returned media are no longer displayed.

This delayed updating is actually desirable in this case, as it allows one to inspect the media currently lying on the library counter and see at once whether these have been registered.

This form structure is significantly easier to use than the previous one with only a single form. However there are still details that can be improved:

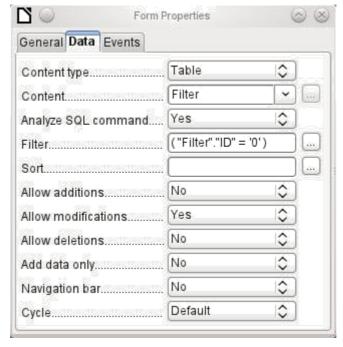

- Media and loan dates might be changed when the media is to be loaned out for longer.
   Changing the media date might make it impossible to trace which item is still available in the library and which is on loan. Changing the loan date could lead to errors. Recall notices could not be verified.
- If a reader record is not selected by clicking on the record header at the left, only the little green arrow on the header shows which record is currently active. It is quite possible that the active record will be scrolled right out of the table control window.
- Instead of the text "Loaned Media of the chosen Reader", it would be better to have the reader's name.
- It is possible to loan out the same medium twice without it having been returned.
- It is possible to delete the record for an item on loan quite easily.
- Data can be changed or deleted in the main form. This can be useful for small libraries
  with little public traffic. However when things become hectic at the loans counter, editing of
  user data should not take place at the same time as issuing loans. It would be better if new
  users could be registered but existing user data left untouched. For libraries, this applies
  equally to deletions or complete name changes.

First let us improve the selection of readers. This should protect us from changes to the loan records. A simple solution would be not to allow any modification except the entry of new records. This still requires a search function when a reader wishes to borrow an item. It would be better to use a list box to find the reader and carry out the issue and return operations in separate table controls.

For the main form we need a table, into which the list box can write a value linked to this table. The table requires an integer field and a primary key. It will always contain only one record, so the primary key field ID can safely be declared as Tiny Integer. The following table named Filter should therefore be created.

Table name: Filter	
Field name	Field type
ID	Tiny Integer, Primary key
Integer	Integer

The table is given a primary key with the value 0. This record will be repeatedly read and rewritten by the main form.

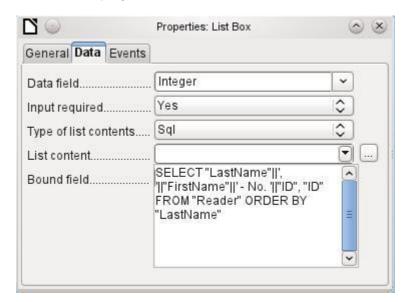

The main form is based on the Filter table. It will just read the value from the table which is associated with the primary key (*ID*) of 0. No data will be added; the current record will just be repeatedly rewritten. As only edits of a single record are allowed, a navigation bar would be superfluous.

This main form is linked to the subform in such a way that the value of the Integer field in the Filter table is the same as the value of the *Reader\_ID* field in the Loan Table. The subform's properties are unchanged from the version shown above.

Before we create a list box in the main form, we must switch off the wizards. The list box Wizard only allows you to create a box that shows the content of a single field; it would be impossible to have surname and given name and an additional number in the display area of a list box. As in the simpler form, we now enter for the list box contents *Surname*, *Given name* – *ID Nr*. The list box transmits the ID to the underlying table.

Next to the list box, a button is created. This button is actually part of the subform. It takes over two functions: saving the record in the main form and updating the table in the subform. It is good enough to entrust the update to the button in the subform. The save process for the modified main form is then carried out automatically.

The button can simply be labeled *OK*. The action assigned to it in the general properties of the button is *Refresh Form*.

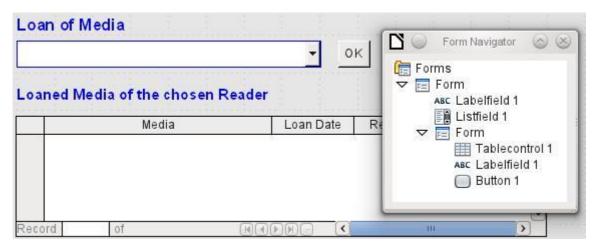

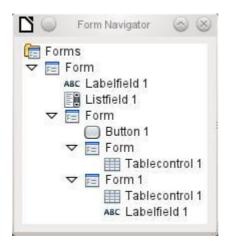

Figure 39: Main form as a filter for a subform

The main form consists only of the heading and the list box; the subform contains another heading, the table control from the previous version and the button.

The form now functions better in that:

- No reader can now be edited, altered or deleted, and
- Readers can be found more quickly by typing into the control than by using a filter.

For a greater degree of functionality (returns without alteration of previous data) a second subform must be created, linked to the same Loans table. To ensure the functionality of the list box in Figure 39, both subforms must be placed one level further down, as subforms of a subform. Data is updated hierarchically from the main form down through the subforms. The button in the previously described form must now be placed in the first subform and not in the two subforms that come under it.

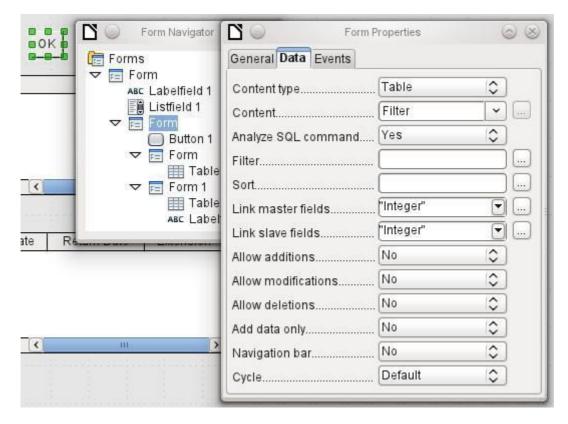

Here the Form Navigator is used to show the different levels. In the main form we have the text field for the form title and the list box for finding the reader. The list box appears at the bottom of the form, as it is declared after the subform. Unfortunately this display sequence cannot be altered. The subform has only one button, for updating its contents and at the same time saving the main

form. One level further down are the two additional subforms. These are given different names when created so that no confusion arises in any level of the tree.

**Note** 

Basically the names of forms and controls are without significance. However if these names are to be accessed by macros, they must be distinguishable. You cannot distinguish identical names at the same level.

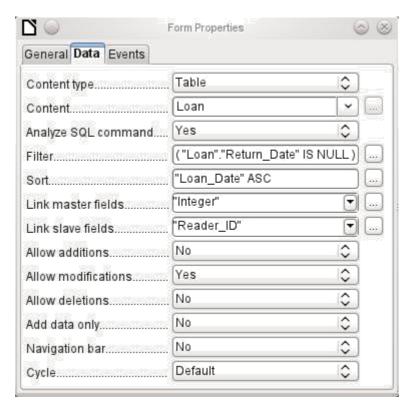

Naturally it makes sense, when creating larger form structures to have meaningful names for forms and their controls. Otherwise finding the right field could quickly become problematic.

The main form and the subform use the same table. In the subform, no data are entered. That is why all the fields for this form are set to *No*. The main form and the subform are linked through the field, whose value is to be transmitted to the sub-subforms: the Integer field in the Filter table.

In the first sub-subform, no existing data are displayed; it is used only for creating new data. For this, the suggested filter is adequate. Only records matching the <code>Reader\_ID</code> and with an empty loan date field ("<code>Loan\_Date"</code> IS NULL) will be displayed. In practice, this means an empty table control. As the table control is not continuously updated, newly loaned media will remain within it until the <code>OK</code> update button is used either to select a new name or to transfer the data into the second sub-subform.

The second sub-subform requires more settings. This form too contains data from the "Loans" table. Here the data is filtered for an empty return date. ("Return\_Date" IS NULL). The data are sorted as in the previous form, so that the media on loan for the longest time are immediately visible.

The following points are also important. Old records can be changed, but no new records can be added. Deletion is also impossible. This is the first necessary step to prevent loan records from being simply deleted later on. But it would still be possible to change the medium and the loan date. Therefore the properties of the columns will require adjustment. Eventually the medium and the loan date should be displayed but protected from modification.

The table control is simply duplicated after the creation of the form. This is done by selecting it, copying, deselecting, and then pasting it in from the clipboard. The copy will be at the same position as the original, and will therefore need to be dragged away. After that, both table controls can be edited separately. The table control for the media return can be left practically the same. Only the write access for the *Media* and *Loan date* columns need to be changed.

While for the Loan date it is only necessary to choose *Read only*, this is not sufficient for list boxes. This setting does not prevent the list box from being used to make changes. However if *Enabled* is set to *No*, a choice cannot be made there. A list box contained within the table control is then displayed as a read-only text field.

In the above table control, all fields that have nothing to do with the loan are removed. Only the medium as a selection field and the loan date *Loan\_Date* remain.

If finally the query for the list box in the upper table control is selected, only those media are displayed which can actually be loaned out. More about this is in Chapter 5, Queries.

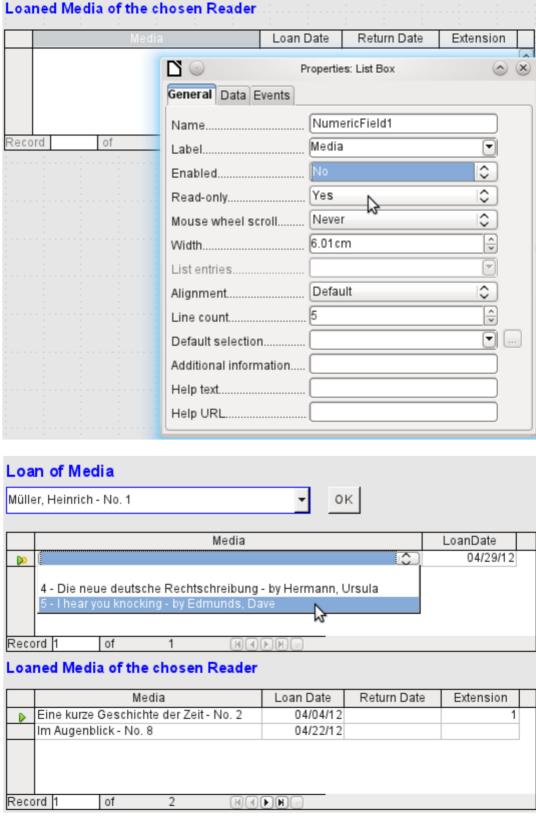

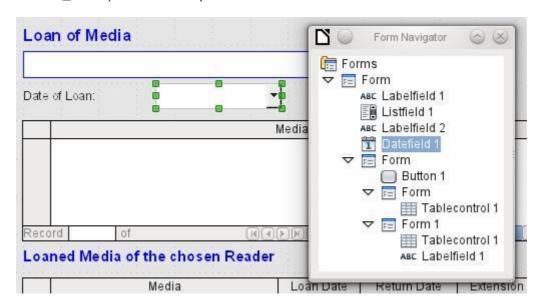

Figure 40: The selection field in the upper subform shows only media that are not on loan.

The media loan form is already significantly more useful. When a reader arrives at the loan counter, his or her name is searched. The media to be loaned can be selected using the list box and the loan date entered. The *Tab* key then takes you to the next record.

A final improvement is also desirable: at present the loan date must be selected each time. Imagine a day in the library with perhaps 200 loan transactions, perhaps just one person, who has to loan out about 10 media each time. That would require the same entry for the date field over and over again. There must be a way to simplify this.

Our main form is linked to the Filter table. The main form works only with the record that has as its primary key the "ID" 0. But additional fields can be built into the Filter table. At present there is no field that can store a date, but we can easily create a new field with the field name Date and the field type *Date*. In the Filter table we now have stored not only the *Reader\_ID* ("Filter"."Integer") but also the *Loan Date* ("Filter"."Date").

In the main form, an additional date field appears, along with a label referring to its content. The value from the date field is stored in the Filter table and transferred by the linkages from subform to sub-subform.

The linkage between the two forms now refers to two fields. The *Integer* field is bound to the *Reader\_ID* field of the sub-subform. The *Date* field is bound to the *Loan\_Date* field. This ensures that the *Loan\_Date* is automatically transferred from the Filter table to the Loans table when the loan is made.

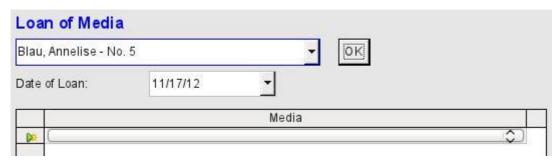

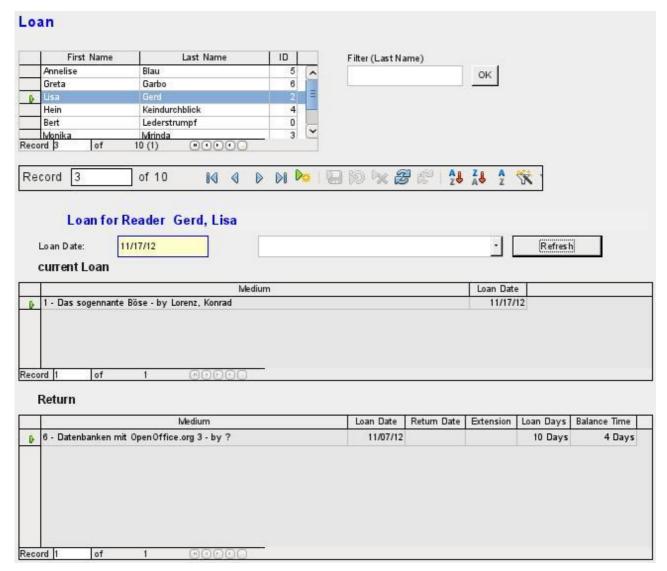

Figure 41: The date of the loan is entered only once. When the Reader changes, it must be reentered.

The date field is now removed from the table control, so that the latter contains only one search field. This would be the ideal requirement for speeding up even more the work of the library. For in fact each medium will have a printed accession number, so why does that have to be searched?

You can just enter the number directly. Or, better still, it could be scanned in with a barcode reader. Then media can be loaned as rapidly as the borrower can stow them in his bag.

This is illustrated in the example database. The above example should suffice for understanding the initial form design but, as the example database, Media\_without\_Macros.odb, develops the form further, the extra refinements are briefly presented below.

The Loan form shows the following properties:

- Readers are displayed in a table control. Here you can also enter new readers.
- Using a filter, linked to the Filter table, names can be filtered using their initial letter. So,
  if you enter A, only people whose surname begins with A will be displayed. This filtering
  is case-independent.
- The subtitle shows again the name of the person to whom the loan is to be made. If a lock has been placed on this borrower, this is also displayed.
- The loan date is set to the current date. This is done in the filter table using SQL such that, when no date is entered, the default value to be stored is the current date.
- Loanable media are selected using a list box. When the Update button is pressed, the loan
  is transferred to the table control below.
- The table control in the middle serves only to display the actual date of loan for the media. Here it is also possible to correct an error retrospectively by deleting the line.

- In the lower table control, as in the above example, alteration of media and loan dates is not possible. Nor is it possible to delete records.
- Apart from the entry of the return date or, if appropriate, an extension of the loan, this table
  also displays the number of days for which the medium can be loaned and how many days
  remain of the current loan period.
- If this remaining time becomes negative, the medium must be returned immediately. The issue is then locked. It becomes possible again only when the medium is returned. After the return, the Update button need only be pressed once.

This form, made by using queries, is significantly more complex in its structure than the previously shown version. You can learn more about the essentials of this in Chapter 5, Queries.
